OPERATIONAL INCIDENT: TORQUE SPIKE & TIGHT HOLE AT 2842.0 M MD

DATE: 2025-08-19 • **DEPTH:** 2842.0 m MD (2802.0 m TVD) • **INCLINATION:** 31.8 deg
FORMATION: Formation-X (Upper Siltstone/Shale Transition)

Description of Event: While drilling at 2842 m MD, rotary torque surged violently from 16.5 kN.m baseline to over 23.2 kN.m. Top drive stalled twice. On picking up string, observed 32 tons overpull. Shaker screen showed excessive volume of splintery cavings indicating wellbore instability.

Action Taken / Mitigation:

1. Picked up string into 9-5/8 in casing shoe at 2150 m MD.
2. Pumped 25 bbl high-viscosity pill with 45 sec funnel viscosity.
3. Reamed tight spot between 2820 m and 2842 m MD with 80 RPM and controlled flow.
4. Mud weight raised from 1.21 SG to 1.24 SG to stabilize brittle shale cavings.
